# Advanced Programming

## 1. Introduction to Functional Programming

IT UNIVERSITY OF COPENHAGEN

**S** SOFTWARE  
**Q** QUALITY  
**R** RESEARCH

- 
- Motivation & Course Goals
  - Basics of Scala, Traits (mixins)
  - Functional Programming Primer
  - Course Organization

# AGENDA

# Apache Spark

## A Motivating Example

- Open-source cluster-computing framework aimed at **Big Data processing**
- Compute queries on large amount of data in **distributed storage**
- **Simple interface**: like local data structures
- **Powerful semantics**: distribution and parallelization
- Originated in 2009 at UC Berkeley, run by **Apache Foundation**
- **600 devs from 200** companies contribute to spark
- **Implemented in Scala**, interfaced to Java, Python, and R
- Key reason of popularity of Scala for Big Data
- Much faster than Hadoop's MapReduce due to heavy use of in-memory operations
- **Some Users**: NBCUniversal, Netflix, Uber, Capital One, Baidu, Salesforce.com, ...

# Count Word Frequency (File)

```
1 object StorageApp:
2
3   def main(args: Array[String]) =
4
5     val conf = SparkConf()
6       .setAppName("SimpleApp")
7       .setMaster("local[6]") // use 6 cores
8     val sc = SparkContext(conf)
9     val lines = sc
10      .textFile("/home/wasowski/opt/spark/README.md", 2)
11      .cache
12
13     val wordCounts = lines
14      .flatMap { line => line.split(" ") }
15      .map { word => (word, 1) }
16      .reduceByKey(_ + _)
17
18     println(wordCounts.collect.map(_._1).mkString)
19     sc.stop()
```

- Resilient distributed dataset (**RDD**)
- `lines` is an RDD of strings
- **Distributed** fault-tolerant processing
- L14 split each line into words, merge into RDD of words
- L15 RDD of words to RDD of pairs
- L16 merge pairs with same word, summing counters (map-reduce)
- We use **collection operations**
- Transformations (`flatMap`, `map`) build **representation of computation**.
- Transformations are **lazy**.
- Actions (`reduceByKey`) are **eager**: execute (**force**) representations
- **Pure** program, no vars&side effects
- `cache` only works if you have **referential transparency**

# Things go wrong with side-effects

Side effects are officially banned in this course!

```
1 var counter = 0
2 var rdd = sc.parallelize(data)
3 // Wrong: Don't do this!!
4 rdd.foreach(x => counter += x)
```

- Line 2: we parallelize a computation
- Line 4: we sum values from an RDD incrementing a counter
- This cannot be done in a distributed way!!!
- Each node gets a **closure** containing the counter, the closure is sent to nodes.
- Each node increments a different copy of the counter!
- This is why we use functions like map and reduceByKey instead of variables

# Count Word Frequency in a Real-Time Data Stream

```
1 object StreamingApp:
2
3   def main(args: Array[String]) =
4     val sparkConf = SparkConf()
5       .setAppName("StreamingApp")
6       .setMaster("local[6]")
7     // Sample every second
8     val ssc = StreamingContext(sparkConf, Seconds(1))
9     val lines = ssc.socketTextStream("localhost", 9999,
10                                     StorageLevel.MEMORY_AND_DISK_SER)
11
12     val wordCounts = lines
13       .flatMap {line => line.split(" ")}
14       .map { word => (word, 1) }
15       .reduceByKey(_ + _)
16
17     wordCounts.print // Nothing gets printed!
18     ssc.start        // The computation starts here
19     ssc.awaitTermination
```

- L12-L15: identical **algorithm**
- Because the DStream **interface** is the same as RDD's
- RDDs and Streams are **monads**
- We will understand this style of API really deeply
- `reduceByKey` needs a commutative associative operator (a **monoid**)
- `+` is a monoid on integers
- L12-L17 builds a **representation of computation**
- L18: streaming starts, before this **nothing happens**
- L17 printing every 1s until killed

# Introduction to Scala I

- A rich modern OO programming language with a functional part; eager by default, statically typed
- Compiles to JVM, compatible with Java on byte code level
- Designed by prof. Martin Odersky at EPFL in Lausanne
- First official release in 2004
- **This is not a course about Scala**, we use Scala to learn concepts that apply to other languages (F#, Haskell, Ocaml, Java, Python, Ruby, etc)

# Basics of Scala

A singleton class and its only instance

**object** creates a name space; used to build modules. Access the namespace with navigation: `MyModule.abs(42)`

```
1 object MyModule:
3   def abs(n: Int): Int =
4     if n < 0 then -n else n
6   private def formatAbs(x: Int) =
7     s"The absolute value of $x is ${abs (x)}"
9   val magic: Int = 42
10  var result: Option[Int] = None
12  def main(args: Array[String]): Unit =
13    assert (magic - 84 == magic.-(84))
14    println (formatAbs (magic-100))
```

**def** Defines a function (l.3)

A body **expression** (statements secondary in Scala)

Use indentation if more expressions needed.

A named **value** declaration (final, immutable). Use this a lot.

A **variable** declaration. Avoid.

Instantiation of a generic type

`None` is a singleton "constructor". Construct objects without **new**

Operators are functions, can be overloaded:  
minus is `Int.-(Int) :Int`  
Unary methods can be used infix: `MyModule abs -42` legal

Every value is an object

Line 6 shows an **interpolated** character string

# Traits: Rich or Fat Interfaces

Scala idiom: decompose classes into traits

```
1 // A class with a final property 'name' and
2 // a unary constructor. You can still add
3 // more members like in Java in braces.
4 abstract class Animal(val name: String)

6 // concrete methods
7 trait HasLegs:
8   def run(): String = "after you!"
9   def jump(): String = "hop!"

11 // abstract method
12 trait Audible: def makeNoise(): String
13 // field
14 trait Registered: var id :Int = 0

16 // multiple traits mixed in
17 class Frog(name: String) extends
18   Animal(name) with HasLegs with Audible:
19   def makeNoise(): String = "croak!"
20   // Frog concrete, so provide makeNoise
```

```
1 // Mix directly into an object
2 val f = new Frog("Kaj") with Registered
3 // f: Frog with Registered = $anon$1@88f0bea
4 f.id = 42
5 println(s"My name is ${f.name}")
6 println("I'm running " + f.run())
7 println("I'm saying " + f.makeNoise())
```

	concrete class	abstract class	trait
multiple inheritance	—	—	+
data	+	+	+
concrete methods	+	+	+
abstract methods	—	+	+
constructor arguments	+	+	—

[Horstmann 2012, chpt. 10], [Odersky et al. 2014, chpt. 12] have more info than [Pilquist, Bjarnasson, Chiusano 2022]

# Pure Functions

## Def. Referentially transparent expression ( $e$ )

Expression  $e$  is RT iff replacing  $e$  by its value in programs does not change their semantics

(Java) append an element to a list

```
a.add(5) // non RT
```

value void; substitution is pointless; the meaning is in the references reachable from  $a$  (change over time for the same  $a$ )

(Scala) append to an immutable list

```
val b = Cons(5, a) // RT
```

The value is a list  $b$ , identical to  $a$ , modulo the added head element

## Def. Pure function ( $f$ )

Iff every expression  $f(x)$  is referentially transparent for all referentially transparent expressions  $x$ . Otherwise **impure** or **effectful**.

In practice: **A function is pure if it does not have side effects** (writes/reads variables, files or other streams, modifies data structures in place, sets object fields, throws exceptions, halts with errors, draws on screen, draws random number)

Pure code shows dependencies in interface, good for mocking, testable

# Referential Transparency Poll

Which of the following computations are referentially transparent [in Java]?

- 1 `a = a + 42`
- 2 `a[x] == 42`
- 3 `println("42")`
- 4 `throw DivideByZero()`
- 5 `f(f(x))` if `f` is pure
- 6 `z = z + f(f(x))` if `f` is pure

# Loops and Recursion

## An imperative factorial

```
1 def factorial(n: Int): Int =  
2   var result = 1  
3   for i <- 2 to n do  
4     result *= i  
5   return result
```

Loops compute with effects;  
**cannot be used in pure code**

## Tail recursive, pure factorial

```
1 def factorial(n: Int) =  
2   def f(n: Int, r: Int): Int =  
3     if n <= 1 then r  
4     else f(n-1, n*r)  
5   f(n, 1)
```

call in tail position

Call tails are automatically compiled to  
loops with  $O(1)$  space overhead

## A pure recursive factorial

```
1 def factorial(n: Int): Int =  
2   if n <= 1 then 1  
3   else n * factorial(n - 1)
```

## Example execution

factorial(5)

~> 5 \* (factorial(4))  
~> 5 \* (4 \* (factorial(3)))  
~> 5 \* (4 \* (3 \* (factorial(2))))  
~> 5 \* (4 \* (3 \* (2 \* (factorial(1)))))  
~> 5 \* (4 \* (3 \* (2 \* 1)))  
~> 5 \* (4 \* (3 \* 2))  
~> 5 \* (4 \* 6)  
~> 5 \* 24  
~> 120

call not in tail position

Uses  $O(n)$  stack space;  
Technically exponential  
(for this example)!

## Def. Call in tail position

The caller immediately returns the value of the call

# Anonymous Functions (Values, Literals)

## Literals

```
val l = List(1, -2, 3)
val a = Array(-1, 2, -3)
```

## Function Literals (Anonymous Functions)

We need the same for functions

```
val negative = (x: Int) => x < 0
negative (-42) ~> true
```

Use to create functions in place:

```
l.filter { (x: Int) => x < 0 } ~> ?
a.filter { (x: Int) => x > 0 } ~> ?
```

## Alternative concise syntax

```
(abs) ~> (x: Int) => MyModule.abs(x)
```

Scala distinguishes functions and methods.

We used this syntax before to turn a method into a function (like above).

## Currying and partial application

```
val add2 = (x: Int, y: Int) => x + y
val add = (x: Int) => (y: Int) => x + y
```

a curried function

What is the type of add? What is the value of add(2)(3) ~> ?

Curried functions can be partially applied: val incr = add(1)

a partial application

Type of incr? Value of incr(7) ~> ?

Methods can also be curried: def add(x: Int)(y: Int): Int = x + y

# This Course is About ...

- This is **not a course in which you learn to implement one particular thing** (a data base, a neural network, an IoT controller)
- This is a course that makes you a **better programmer of anything**. Anything can be programed in a pure manner.
- You learn to program **concisely**, in an **organized readable way**
- You learn to use **types** to increase both **safety** and **reuse** in your programs
- You learn to **design uniform standard APIs** that are familiar to other experienced programmers like you
- You learn to **test** your programs much more intensively, with better coverage.
- Concurrency (Akka, ZIO), Computational Graphs (Tensor Flow), Big Data (Spark), Probabilistic Programming (Figaro, PyMC3), Reactive Programming (Rx) are all examples of concrete contexts in which these skills will be useful.
- Sometimes it hurts, but this is because you are growing.

# Course Organization

- Our **website** is LearnIT + a git-repo
- **Reading:** read prescribed book chapters and papers **before class**.
- **Lectures:** 15 weeks. Summarize the main points, but may skip details needed in exercises
- **Exercises (Homeworks):** ca. 13 weeks, (10 graded) same days as lectures
- Individual hand ins, but allowed, even encouraged to discuss with others (**mix across BSc-programs**). You must type your hand-in yourself
- **Exam:** written, need to pass 5 homeworks to be admitted, old exams will be published
- **To pass a homework:** (1) the code must compile and (2) at most 5 tests can fail
- Communicate **in class** on Thursday, daily on the **Teams**, Thursdays in **CS Study Lab**
- Andrzej and Florian are **terrible with email**. Use email only for sensitive personal matters.
- Teachers are **available during exercises for the first 30 minutes**. Each group is strongly encouraged to discuss at least one hand in to get a sense of requirements. Discuss with teachers even if you think you are doing fine.

# In the next episode ...

- Functional Programming 101 continued
- Algebraic data types, pattern matching, higher order functions, polymorphism, folding
- The reading should be relatively easy, so remember to read before class !
